AMSER Case of the Month: August 2020

72-year-old male with acute onset left lower chest pain/left upper abdominal pain

Michael Evans, MD/PhD Student
Tyrell Gardner, MD
Peter Haar, MD/PhD

VCU School of Medicine, Department of Radiology
Patient Presentation

- **HPI:** 72-year-old male presents to the ED with severe, aching left lower chest pain/left upper abdominal pain upon awakening. States that the pain is exacerbated by movement. Endorses nausea but denies vomiting. Denies SOB, recent fever, recent trauma, or other associated symptoms.

- **PMHx:** CAD s/p CABG (2003), HTN, HLD

- **Medications:** aspirin, atorvastatin, lisinopril, metoprolol

- **SocialHx:** active smoker, medication non-compliance

- **Vitals:** BP 73/47, HR 73, RR 20, SpO2 95% on RA, T 36 C

- **Relevant Labs:**
  - **BMP:** Cr 1.25
  - **CBC:** WBC 14.2, Hgb 11.0, Plt 174
  - **Coags:** PT 22.8, PTT 53, Fibrinogen 166
  - **EKG and Troponins:** unremarkable
What Imaging Should We Order?
ACR Appropriateness Criteria

Clinical Condition: Acute Chest Pain — Suspected Aortic Dissection

<tr>
<td>X-ray chest</td>
<td>9</td>
<td>This procedure should be performed if readily available at the bedside and if it does not cause delay in obtaining a CT or MRI scan. Alternative causes of chest pain may be discovered. This is not the definitive test for aortic dissection.</td>
<td>🟦</td>
</tr>
<tr>
<td>CTA chest and abdomen with IV contrast</td>
<td>9</td>
<td>This procedure is recommended as the definitive test in most patients with suspicion of aortic dissection.</td>
<td>🟦</td>
</tr>
<tr>
<td>MRA chest and abdomen without and with IV contrast</td>
<td>8</td>
<td>Test procedure is an alternative to CTA for contraindication to CT (iodinated contrast), multiple prior chest CTA for similar symptoms, and in patients showing no signs of hemodynamic instability. Scanner availability and local expertise limit widespread use, as there is potential for delay in diagnosis.</td>
<td>O</td>
</tr>
<tr>
<td>US echocardiography transesophageal</td>
<td>8</td>
<td>Consider this procedure if a skilled operator is readily available.</td>
<td>O</td>
</tr>
<tr>
<td>MRA chest and abdomen without IV contrast</td>
<td>7</td>
<td>This procedure is an alternative to CTA for patients with contraindication to both iodinated and gadolinium contrast agents, such as in patients with renal failure, patients with multiple prior chest CTA for similar symptoms, and in patients showing no signs of hemodynamic instability. Scanner availability and local expertise limit widespread use, as there is potential for delay in diagnosis.</td>
<td>O</td>

Rating Scale: 1,2,3 Usually not appropriate; 4,5,6 May be appropriate; 7,8,9 Usually appropriate

The ER physician suspected Aortic Dissection

This imaging modality was ordered by the ER physician
Findings: (unlabeled)
Findings: (labeled)

- Normal takeoff and filling of brachiocephalic, left common carotid, and left subclavian arteries from aortic arch.
- Normal diameter of ascending and descending thoracic aorta with no sign of dissection.
- Abdominal aortic aneurysm measuring 7.7 cm in diameter.
- Evidence of hemorrhage prior to contrast administration.
- Aneurysmal dilatation of R and L common iliac arteries measuring 4.3 cm and 3.4 cm respectively.
- Mural thrombus within the aneurysms.
- Extravasation of contrast indicating active bleeding.
- Evidence of hemorrhage prior to contrast administration.
Findings: (labeled)

Abdominal aortic aneurysm with length of 12.8cm

Mural thrombus

Normal caliber of abdominal aorta above renal arteries

Coronal image demonstrating extent of aneurysmal dilatation from just below the renal arteries to the aortic bifurcation

Left renal artery

Aneurysmal dilatation of L and R common iliac arteries
Final Dx:

After initial concern for aortic dissection, a ruptured abdominal aortic aneurysm (AAA) was found on CTA: Abdomen
Case Discussion: Abdominal Aortic Aneurysm

- **Definition:** AAA is defined as localized dilatation of the abdominal aorta that is >50% of its normal diameter.
  - Normal infrarenal aorta = 2 cm. *(Any diameter ≥3 cm is considered aneurysmal)*
  - AAA are described based on their relation to the renal arteries as suprarenal, pararenal, juxtarenal or infrarenal with up to 40% extending to involve the iliac arteries (as in this case)

- **Epidemiology and Risk Factors:**
  - Age > 50, male gender, hypertension, cardiovascular/atherosclerotic disease, family history and Caucasian race are important risk factors with smoking being the most important modifiable risk factor
  - The estimated prevalence of AAA 2-8% with an annual incidence of 0.4-0.67%

- **Clinical Presentation:**
  - Most patients with AAA present asymptptomatically with diagnosis by screening or as an incidental finding on imaging
  - Symptomatic AAA presents as a pulsatile abdominal mass or as new onset abdominal, back or flank pain
  - Ruptured AAA presents with severe back or abdominal pain, hypotension and a pulsatile abdominal mass in only 50% of patients
    - Only 20-30% of patients who present with ruptured AAA have a known history of AAA
    - Other diagnoses such as aortic dissection (as in this case), renal colic, diverticulitis, or bowel perforation may be initially suspected
Case Discussion: Abdominal Aortic Aneurysm

• Screening and Diagnosis:
  • The USPSTF recommends 1-time screening for AAA with ultrasonography in men aged 65-75 years with any smoking history
  • ACR Appropriateness Criteria® for suspected AAA and surgical planning for treatment of AAA:

![Image of American College of Radiology Appropriateness Criteria]

• Management: AAAs are managed according to diameter and the presence of symptoms
  • Asymptomatic:
    • Patients with AAA < 5.5 cm are monitored with yearly ultrasound
    • If aneurysm reaches size ≥ 5.5 cm or is expanding at a rate >1 cm/year elective repair (endovascular vs. open) is indicated
    • No medical therapy has been proven to reduce the rate of aneurysmal enlargement
  • Symptomatic/Ruptured:
    • Aneurysm repair is indicated in symptomatic patients (endovascular vs. open)
    • Hemodynamically unstable patients presenting with rupture are taken for immediate resuscitation and open repair (as in this case)
